# Week 10, Lecture 2

## Intended Learning Outcomes

- Understand the physiological basis of parathyroid hormones (PTH)
- Understand the mechanism of action of PTH
- Understand the action of calcitonin

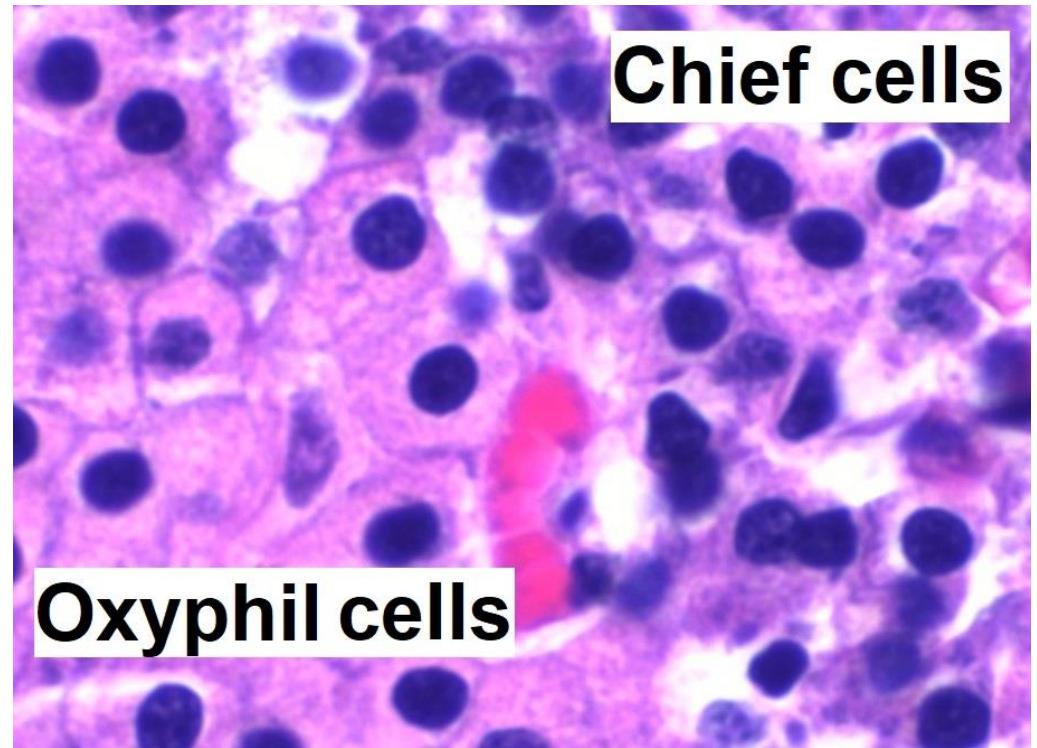

## Parathyroid glands

- Four parathyroid glands on the posterior aspect of the thyroid gland.
- Each measures 3-5 mm in diameter
- The weight of the 4 glands about 120 mg.
- Secrete parathormone (PTH, 84 aas)
- The normal plasma level of PTH is about ***1.5 to 5.5 ng/dL***.
- Which is essential for life
- Have important role in the regulation of  $\text{Ca}^{2+}$  metabolism in the body.

# Parathyroid glands

- The parathyroid glands are formed of columns of ***chief cells*** and ***oxyphil cells***:
  - a) **The chief cells:** More numerous and secrete the **PTH**.
  - b) **The oxyphil cells:** appear in the gland at 10th year of life.
  - These cells represent inactive chief cells.
  - The function of the oxyphil cell is not known. It is believed that oxyphil cells are the degenerated chief cells.

# Functions of Parathormone

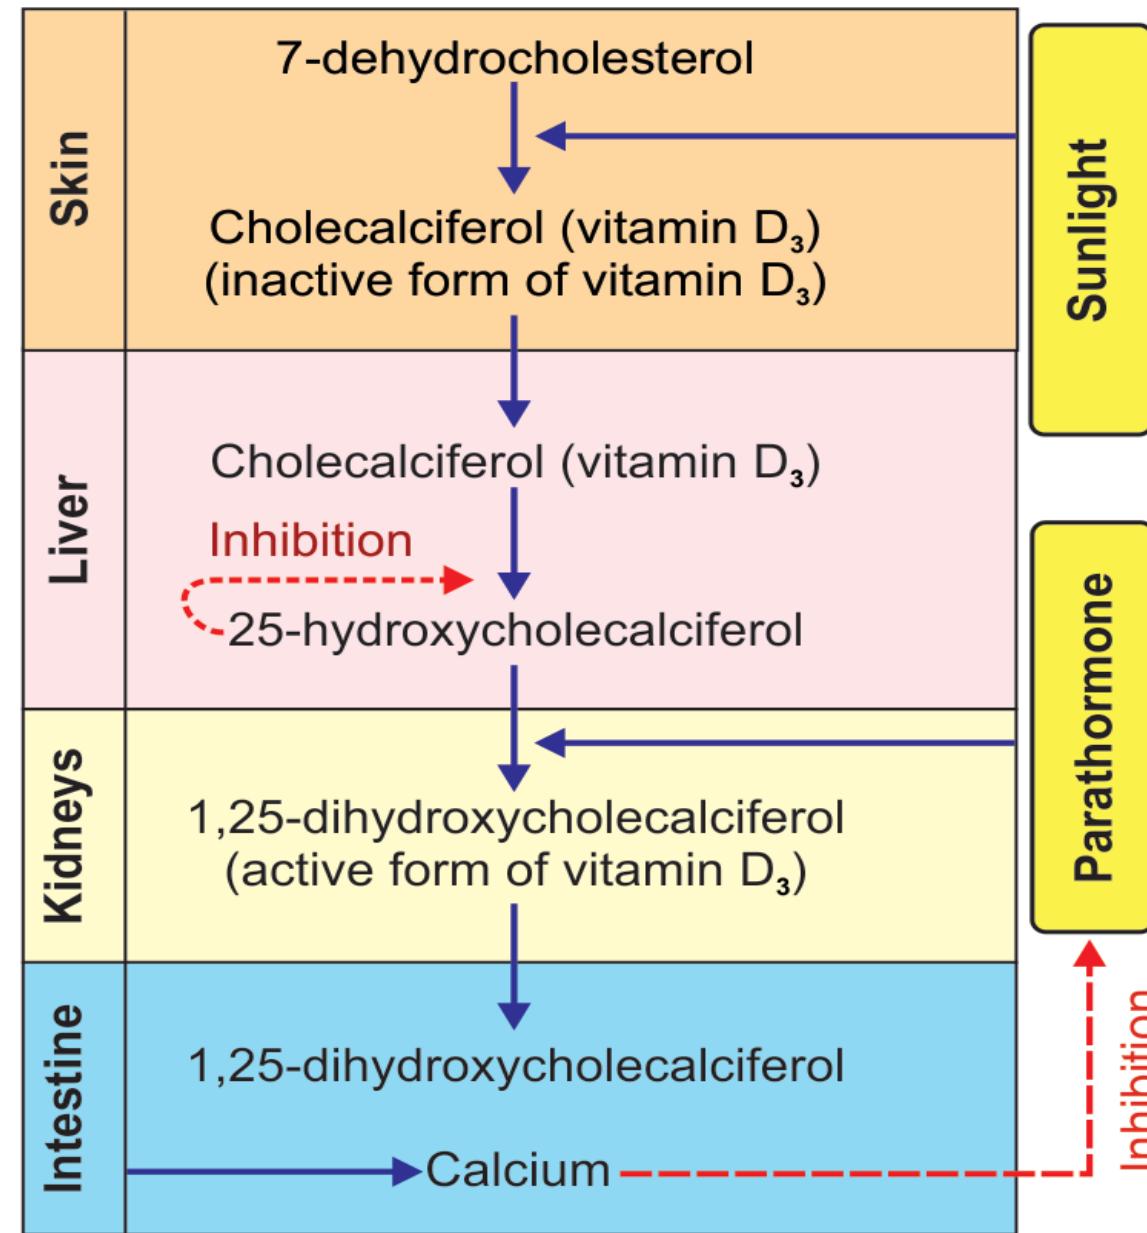

- The main function is to keep a **normal plasma  $\text{Ca}^{2+}$  level (9-11 mg %).**
- It increases the blood  $\text{Ca}^{2+}$  level.
- It maintains a constant ratio between plasma  $\text{Ca}^{2+}$  &  $\text{PO}_4$
- **How does PTH perform these effects?**

## A. On the small intestine

- Increases the absorption of  $\text{Ca}^{2+}$  , mediated by active vitamin D (1,25 dihydroxy cholecalciferol)
- Increases the absorption of  $\text{PO}_4$  and Mg.

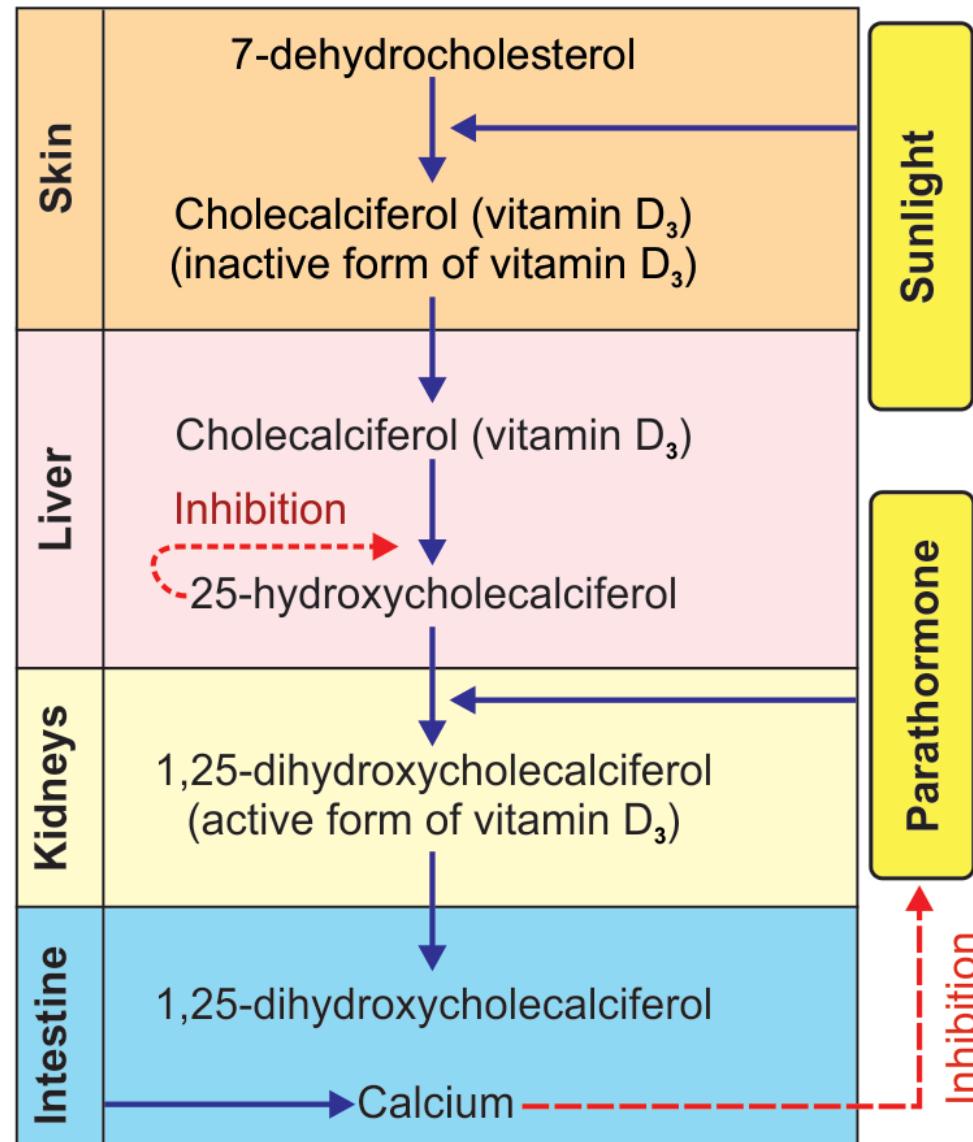

# Functions of Parathormone

- Activation of vitamin D: the most important one is **vitamin D<sub>3</sub>**. It is also known as cholecalciferol.
- Vitamin D<sub>3</sub> is synthesized in the skin from 7-dehydrocholesterol by the action of ultraviolet rays from the sunlight.
- **The activation of vitamin D<sub>3</sub> occurs in two steps .**
- **The first step:** cholecalciferol (vitamin D<sub>3</sub>) is converted into 25-hydroxycholecalciferol in the liver.

# Functions of Parathormone

- **The second step:** 25-hydroxycholecalciferol is converted into 1,25-dihydroxycholecalciferol (**calcitriol**) in the kidney,
- **It is the active form of vitamin D<sub>3</sub>.** This step needs the presence of PTH.
- The 1,25-dihydroxycholecalciferol increases the absorption of calcium and phosphate from intestine.

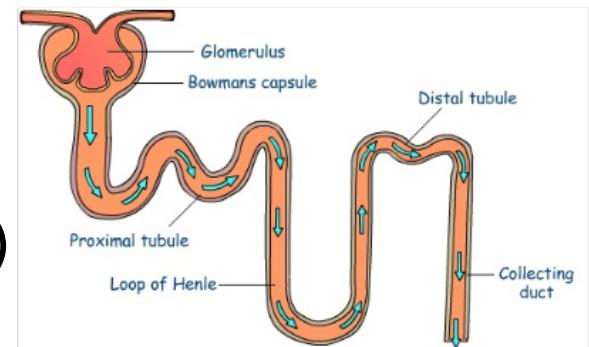

Schematic diagram showing activation of vitamin D

# Functions of Parathormone

## B. On the kidney

- **On the ascending limb of the loop of Henle and distal CT:** Increases the reabsorption of  $\text{Ca}_{2+}$  & increases  $\text{PO}_4$  excretion.
- **On the proximal CT**
  - Increases the reabsorption of Mg
  - Activates vitamin D to (1,25 dihydroxycholecalciferol)

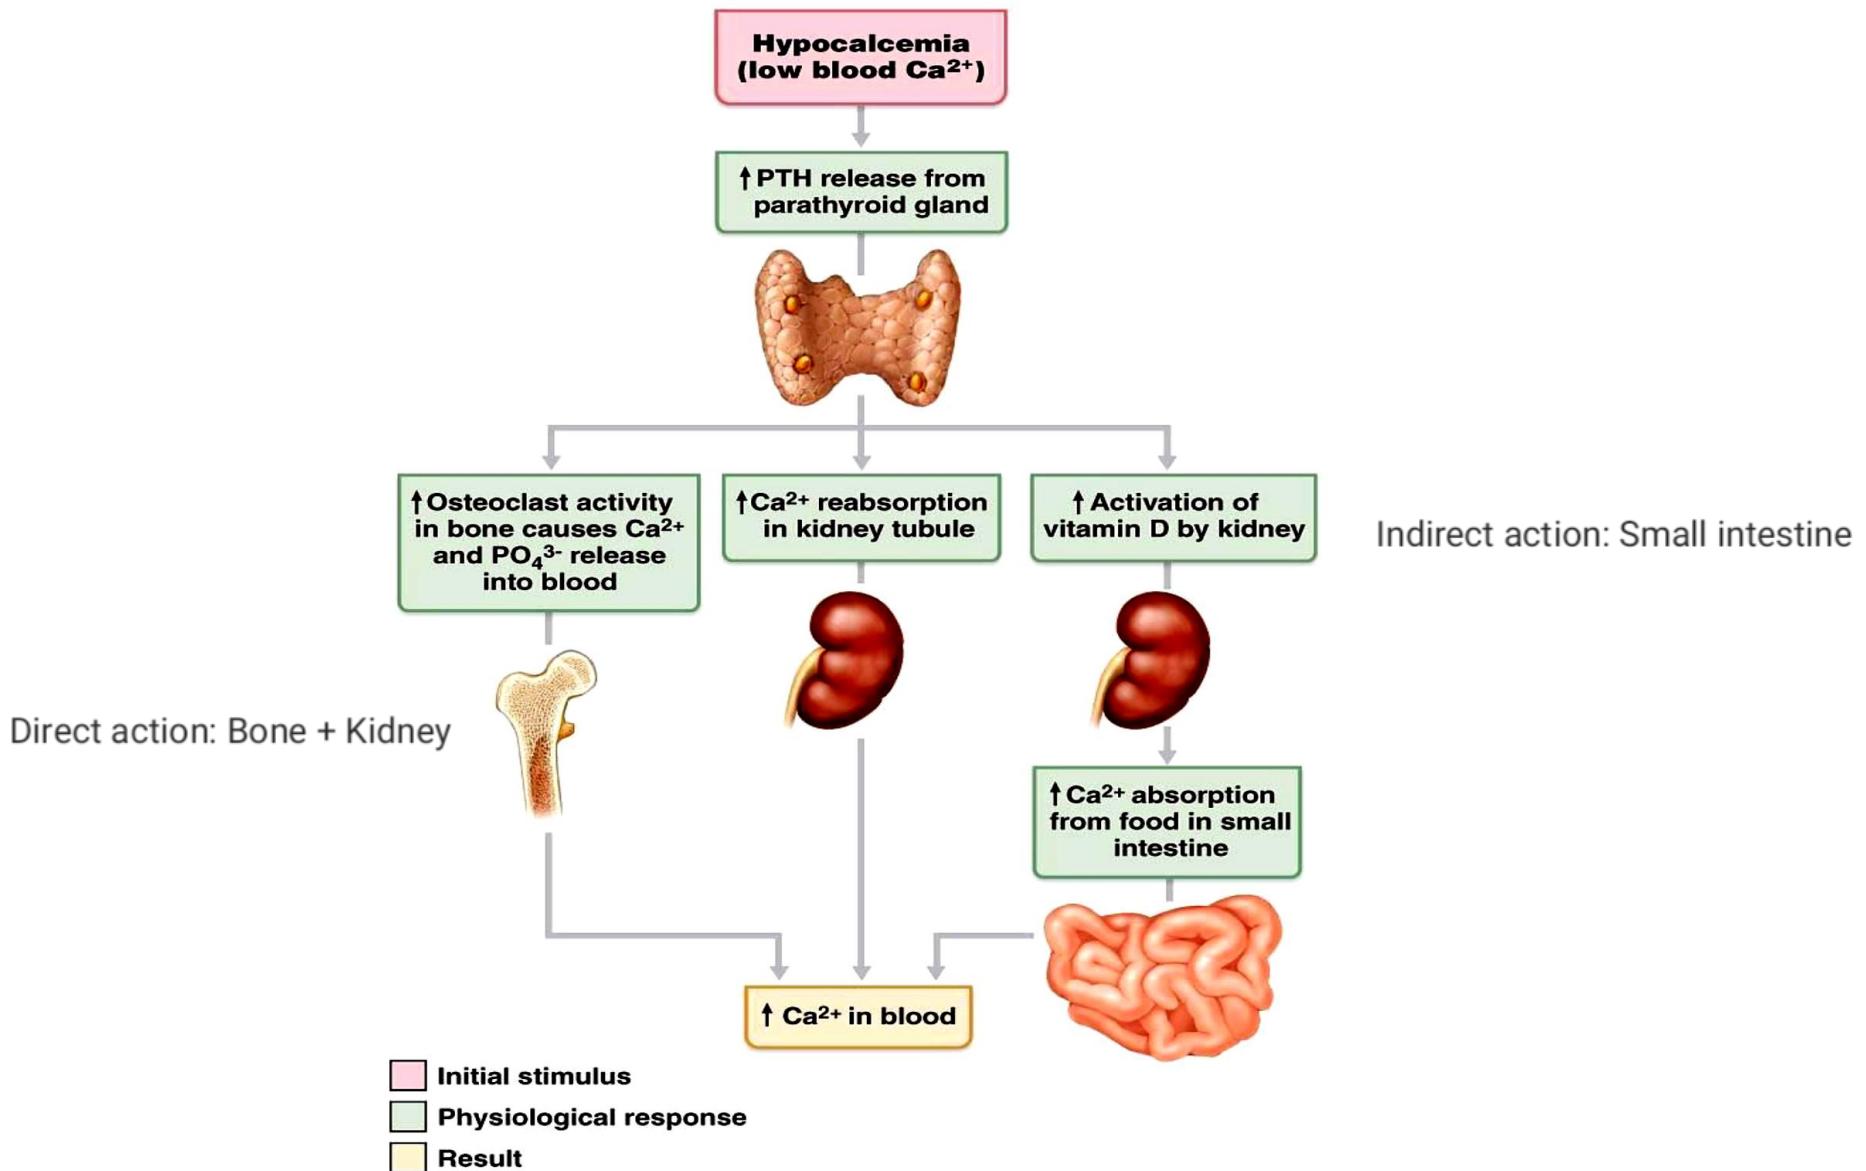

Convoluted tubule

## C. On the bone

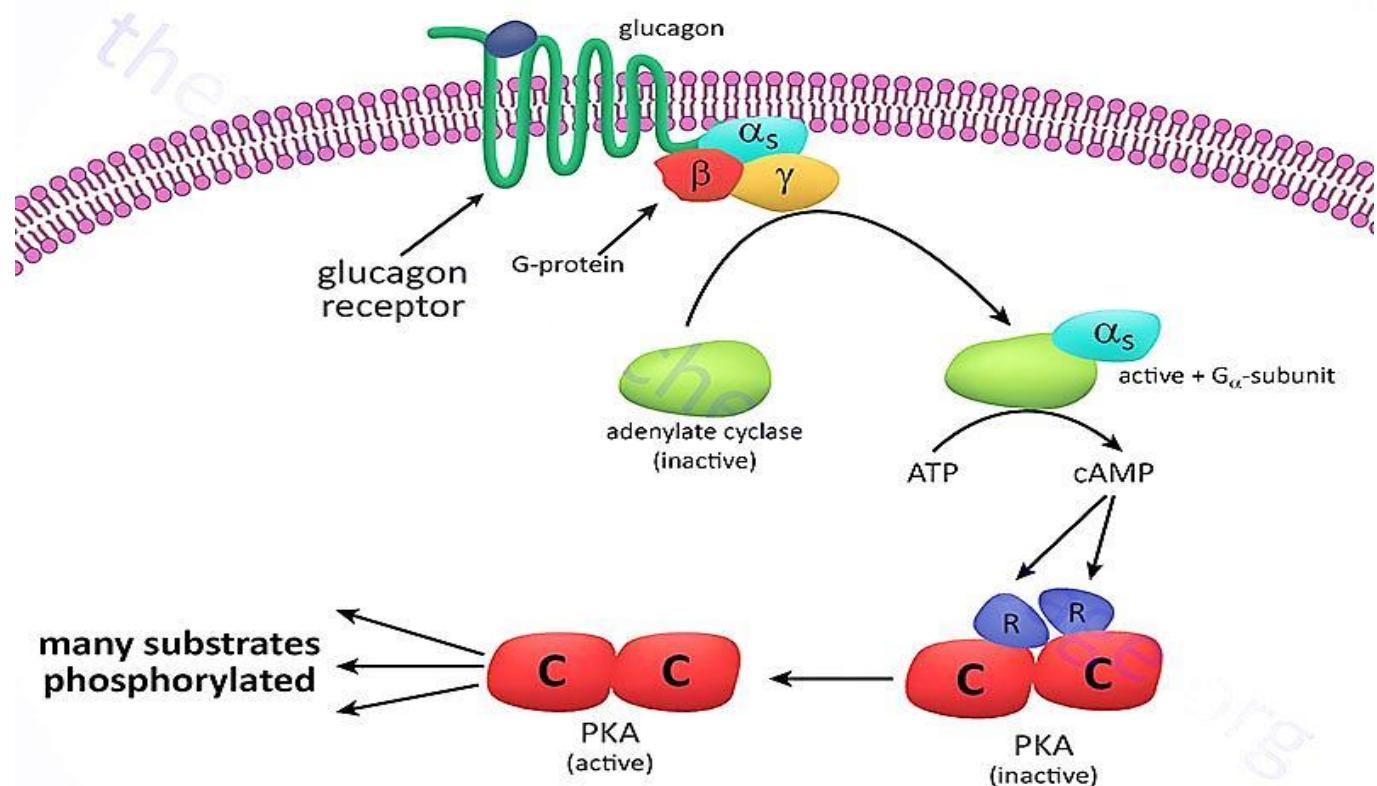

- Increases the number and activity of osteoclasts (bone destroying cells)
- This results in:
  - resorption of bone
  - release of  $\text{Ca}^{2+}$  into the blood and
  - hypercalcemia.

# Functions of Parathormone

## Mechanism of action of Parathormone

- Through cell membrane receptor:
- Activation of adenyl cyclase enzyme & increase the intracellular cAMP.
- Increase intracellular  $\text{Ca}^{2+}$  , where it acts as a second messenger or modulate adenyl cyclase response

# Calcitonin

- **Site of secretion**
  - Calcitonin is secreted by the parafollicular cells or clear cells (C cells) situated amongst the follicles in the thyroid gland.
- **Chemistry and plasma level**
  - It is a polypeptide chain with 32 amino acids.
  - Its molecular weight is about 3,400.
  - Plasma level of calcitonin is 1 to 2 ng/dL.

## Actions of Calcitonin

- **On Blood Calcium Level**
- Plays an important role in the control of the blood calcium level.
- It decreases the blood calcium level and thereby counteracts parathormone.
- Calcitonin reduces the blood calcium level by acting on bones, kidneys and intestine.

# Actions of Calcitonin

## A. On the bones

- Calcitonin stimulates osteoblastic activity and facilitates the deposition of calcium on bones.
- At the same time it suppresses the activity of osteoclasts.
- It inhibits the resorption of calcium from bones.
- It inhibits even the development of new osteoclasts in bones.

# **Actions of Calcitonin**

## **B. On the kidney**

- It increases the excretion of calcium through the urine, by inhibiting the reabsorption of calcium from the renal tubules.

## **C. On the intestine**

- It prevents the absorption of calcium from the intestine into the blood.

# Actions of Calcitonin

- **On Blood Phosphate Level**
- With respect to calcium, calcitonin is an antagonist to PTH.
- But it has similar actions of PTH with respect to phosphate.
- It decreases the blood level of phosphate by acting on bones and kidneys.

## A. On the bone

- It inhibits the resorption of phosphate from bone and stimulates deposition of phosphate on bones.

## B. On the kidney

- It increases the excretion of phosphate through urine, by inhibiting the reabsorption of calcium from the renal tubules.

# Regulation of Calcitonin secretion

- High calcium content in the plasma stimulates calcitonin secretion through calcium receptors in parafollicular cells.
- Gastrin also is known to stimulate release of calcitonin.
